Rec'd PCT/PTO   15 APR 2005

CUSTOMIZED TRANSITION ZONE
SYSTEM AND METHOD FOR AN ABLATION PATTERN

The present invention relates generally to eye surgery, and more particularly to a
5 corneal refractive procedure providing a customized transition zone, which exhibits
continuous curvature between an ablated optical zone and a non-ablated zone to address
curvature discontinuity at the edge of the optical zone, thereby minimizing the
biomechanical response and its post-operative effects on vision.

Approximately 60% of Americans have refractive errors, and millions of people
10 are myopic worldwide. Thousands of laser refractive surgeries are performed every year
for the correction of myopia. Of the many individuals treated, about 15% to 50% do not
achieve 20/20 vision due, at least in part, to the relationship of the patient eye to the
mean population response eye, the dependence of refractive procedures on the mean
population response eye, and ablation patterns that do not take advantage of the widest
15 possible ablation zone achievable biomechanically. Additionally, many individuals
cannot benefit from conventional corneal ablative techniques because their eyes do not
fall within parameters modeled by the mean population response eye. For example,
using conventional techniques, some corneas are not thick enough for a desired
correction.

20   Early attempts at photorefractive keratectomy (PRK) modeled the cornea as two
refracting surfaces with a bulk material in between the two refracting surfaces where
there was a known index of refraction. In treating myopia, the goal was to increase the
anterior radius of curvature, thus decreasing the curvature of the anterior surface. A
simple geometric formula resulted, which assumes that the targeted corneal shape was a
25 function of the ablation profile. This is the "shape subtraction" paradigm which assumes
that the final corneal shape is determined by how much tissue is subtracted (ablated) by a
laser. Essentially, this model treats the cornea as a piece of plastic to be sculpted into an
ideal surface shape by laser ablation.

For example, Figure 1 is a schematic of the simple "shape-subtraction" paradigm
30 for correcting myopia where the cornea is initially "too curved" and thus is

conventionally "reshaped" towards a desired "flatter" profile. R_1 and R_2 are initial and final radii of curvature, respectively, d is the maximum ablation depth, and S is the diameter of the optical zone. In some conventional processes, the starting point in determining how much material is to be removed from the center of the cornea to change

5 its curvature is determined by the following geometric formula, the Munnerlyn formula: $d = R_2 - sqrt(R_1{}^2 - h^2) - R_2 + sqrt(R_2{}^2 - h^2)$, where $R_1 - sqrt(R_1{}^2 - h^2)$ is the distance of center front from origin, and R2 is the new desired radius of curvature. In other conventional processes, the starting point within the optical zone is an approximation of the Munnerlyn formula, which says that $d = DS^2/3$ where D is the amount of desired

10 diopter treatment and S is the optical zone, which is equal to 2h. As typically used, this approximation calls for a 12-micron depth ablation of corneal tissue per diopter of treatment over a 6.0 mm chord treatment zone.

Figure 2 is another schematic diagram of the shape-subtraction model of refractive surgery for a myopic ablation. The pre-operative radius of curvature is R_1 and

15 the desired post-operative curvature is R_2. The intervening tissue between the pre-operative curve (solid) and post-operative curve (dashed) is "subtracted" with an excimer laser to produce the desired result. Thus, conventionally, corrections are limited by the amount and/or character of ablation that can occur within the optical zone. The shape subtraction model assumes that the only portion of the cornea that is changed during an

20 ablative procedure is the area within the ablation zone and that even if there are changes outside the ablation zone; they have no effect on central vision. Thus, ablation patterns conventionally do not account for the corrective effect outside the optical zone caused by the biomechanical response of the cornea to the operative procedure. While the shape subtraction model has yielded satisfactory results without considering the biomechanical

25 response of the cornea to perturbation, it can be improved.

Additionally, the conventional reshaping in the conventional optical zone of a cornea has unanticipated and undesired results. By way of illustration shown in Figure 3, the edge of optical zone S where the ablated cornea meets the non-ablated cornea is a both a slope and a curvature discontinuity (i.e., points where the first and second

30 derivatives along a programmed contour are step functions), which results in various

-3-

visual problems including, but not limited to, spherical aberration, glare and halo effects. These effects can be particularly acute in low light conditions when the pupil enlarges. It is to be appreciated that the larger the difference between R_1 and R_2, the greater the slop and curvature discontinuities.

5   Conventionally, a transition zone is added to ablation patterns used in regular procedures and "customized" procedures (e.g., those based on topographical and/or wave-front analyses). As shown by Figure 4, the transition zone is defined as the area between programmed optical zone S_1 and the ablation zone S_2 used for the corrective procedure. For example, a one or two millimeter wide transition zone is added to a
10 conventional (e.g., six millimeter) optical zone for a total ablation pattern of around eight millimeters.

Conventional transition zones are typically linear or stepwise reduction patterns sized to be completed in the allocated transition zone width. Although such conventional transition zones reduce the abrupt change in slope between the "programmed" optical
15 zone (i.e., area of cornea ablated for corrected measures) and non-ablated cornea in an attempt to minimize the above-mentioned visual problems, they are not thought to contribute to the corrective effect and improved image quality anticipated by ablation in the optical zone. Additionally, such conventional transition zones still have a curvature discontinuity and high curvature that generates a spherical aberration. Furthermore, the
20 corrective effect of the transition zone on vision is not conventionally accounted for in conventional or customized procedures. Moreover, both regular conventional procedures and customized conventional procedures are limited by the amount of available cornea to ablate. Conventionally, the wider the optical zone is made, the deeper is the depth of ablation. Understandably, there is a finite amount of corneal depth to ablate, and thus,
25 with conventional patterns, a finite ablatable width. For example, Figure 5 illustrates two sample depths for two sample optical zone widths. To illustrate, for a desired ten or twelve diopter myopic correction, with a 500 micron thick cornea, conventional patterns may be limited to a 4.5 mm optical zone before running out of ablatable cornea. For a desired correction, 4.5 mm may not be wide enough even with a 1.5mm conventional

-4-

transition zone, and induce glare, and/or halos and/or spherical aberration. Thus, conventional methods may not produce the desired correction.

Accordingly, there is room for more improvement based on the methods and systems described herein.

5   In one embodiment, a corneal ablative pattern based on individual biomechanical responses to cutting, ablating and/or peeling a cornea is disclosed. The corneal ablative pattern includes a wider correction zone that includes both an optical zone and a transition zone, where the transition zone has a continuous curvature and its effects on vision correction are accounted for in the pattern design. The individual biomechanical

10   responses can be predicted from pre-operative measurements and/or from measurements taken during surgery such as for example, after a flap cut during laser in-situ keratomileusis (LASIK). The individual biomechanical responses can depend on significant differences in the material properties of living human corneas and thus, there are significant differences in the responses of various individuals to similar ablative

15   profiles.

Since a flap is cut in a LASIK procedure, the biomechanical responses of the cornea to the cut can be employed to predict a biomechanical response to ablation. Thus, measurements taken before and after cutting the flap facilitate adapting parameters for subsequent ablative steps. The prediction can be facilitated by reference to a

20   biomechanical response model that relates inputs to outputs in light of a plurality of relationships between corneal measurements and individual responses that lead to post ablative corneal shape. In procedures like those where no flap is cut, such as for example, LASEK and PRK, predictions about biomechanical responses can still be made based on pre-operative measurements and a biomechanical response model.

25   In another embodiment, a method for improving a transition zone is disclosed. The method comprises measuring a peripheral curvature of a pre-operative cornea, and developing an ablation depth profile in a transition zone, where the ablation depth profile will produce a continuous curvature on the surface of a post-operative cornea, where the curvature will be continuous through the transition zone.

-5-

In still another embodiment, a system for customizing an ablative pattern design with an improved ablation zone comprising both an ablated optical zone and an ablated transitional zone of continuous curvature is disclosed. The system comprises means for acquiring a pre-operative data by measuring a cornea pre-operatively, and means for
5 acquiring a post-perturbation data by measuring a cornea after a perturbation has been applied to the cornea. The system further includes means for acquiring a prediction data of the biomechanical response of a cornea to ablation based, at least in part, on the pre-operative data and the post-perturbation data, and means for designing an ablation pattern based, at least in part, on the prediction data, where the ablation pattern considers
10 the corrective effect of a transition zone.

In still another embodiment a method for customizing a transition zone for a refractive ophthalmic treatment is disclosed. The method comprises measuring a curvature of a pre-operative cornea. The method further includes developing an ablation depth profile in a transition zone, where the ablation depth profile will produce a
15 continuous curvature on the surface of a post-operative cornea, where the curvature will be continuous throughout the transition zone thereby minimizing curvature discontinuities.

In yet another embodiment, a system for customizing a transition zone of an ablation pattern for a refractive ophthalmic treatment for a cornea is disclosed. The
20 system comprises a data receiver for receiving a corneal data. The system further includes a transition zone designer adapted to produce the customized transition zone with a continuous curvature which eliminates curvature discontinuities at or near the edge of a post-operative optical zone and whose effects minimizes the biomechanical response in the post-operative cornea.

25 In another embodiment, a method to facilitate an increased functional optical zone with a customized transition zone pattern of continuous curvature, where the corrective properties of the transition zone are included in the ablation zone pattern design is disclosed. The method comprises receiving pre-operative data concerning a cornea on which a refractive ophthalmic treatment will be performed, and subtracting the
30 programmed optical zone correction from corneal measurements provided in the pre-

-6-

operative data to provide location of the programmed optical zone edge. The method
further includes calculating the predicted curvature at and/or near the edge of the optical
zone after application of the programmed optical zone correction, and calculating based,
at least in part, on the pre-operative data received and the predicted curvature at the edge,

5   a customized transition zone pattern. The customized transition zone addresses curvature
discontinuity by eliminating its occurrence in and/or near the programmed optical zone.
The method also includes applying the calculated transition zone to the ablation zone
pattern.

    These and other features and advantages of the invention will be more fully

10 understood from the following description of preferred embodiments of the invention
taken together with the accompanying drawings. It is noted that the scope of the claims
is defined by the recitations therein and not by the specific discussion of features and
advantages set forth in the present description.

    The following detailed description of the embodiments of the present invention

15 can be best understood when read in conjunction with the following drawings, where like
structure is indicated with like reference numerals and in which:

    Figure 1 illustrates a shape subtraction model.

    Figure 2 illustrates a shape subtraction model of refractive surgery for myopic
ablation.

20   Figure 3 illustrates a transition between an ablated area and a non-ablated area
having curvature discontinuities.

    Figure 4 illustrates a conventional transition zone between an ablated area and a
non-ablated area.

    Figure 5 illustrates two different ablation widths and the corresponding ablation

25 depths.

    Figure 6 illustrates a conceptual model for predicting biomechanical central
flattening due to severing corneal lamellae.

    Figure 7 illustrates a conceptual model of an ablation pattern comprising a
customized transition zone modifying a programmed optical zone correction according

30 to the present invention.

-7-

Figure 8 is a schematic block diagram of an illustrative computing environment that supports the methods and systems described herein.

Figure 9 is a flow chart of an example method for designing a customized transition zone pattern.

5   Figure 10 is a schematic block diagram of an example system for designing a customized transition zone pattern.

Figure 11 illustrates a simulated tangential map and a simulated refractive power map for a cornea before ablative surgery.

Figure 12 illustrates a simulated tangential map and a simulated refractive power 10 map for a cornea following a conventional ablative procedure.

Figure 13 illustrates a simulated tangential map and a simulated refractive power map for a cornea following an ablative procedure that employs the systems and methods described herein for an improved transition zone.

Skilled artisans appreciate that elements in the figures are illustrated for 15 simplicity and clarity and have not necessarily been drawn to scale. For example, the dimensions of some of the elements in the figures may be exaggerated relative to other elements to help to improve understanding of embodiment(s) of the present invention.

The corneal ablative pattern described herein provides a wider ablation zone that includes both an optical zone and a transition zone, where the transition zone has a 20 continuous curvature and its effects on vision correction are accounted for in the pattern design. It is to be appreciated that post-ablative corneal shape, and thus visual performance, is the function of at least three factors: the ablation profile, the healing process, and the biomechanical response of the cornea to structural change.

Furthermore, there are only certain shapes a cornea will biomechanically assume. These 25 shapes depend, at least in part, on epithelial thickness, stromal thickness and response to severing stroma and/or lamellae. For example, the deeper the ablation in the edge of the ablation zone in a myopic procedure to generate a potentially desirable post-operative prolate shape, the greater the number of severed lamellae and the greater the biomechanical central flattening response to counter the effect. The transition zone of 30 the present invention considers such factors.

-8-

LASIK, LASEK, and/or PRK procedures can be improved by taking pre-operative measurements of the eye, predicting the cornea's biomechanical response to ablative treatment, and customizing an ablative pattern design. Additionally, wave-front guided procedures may also employ a transition zone that may benefit from the systems

5 and methods described herein. Parameters considered in customizing the ablation pattern design with an improved transition zone include, but are not limited to, the location, size, shape, depth, and number of cuts and/or ablations. In addition to pre-operative measurements, real time measurements taken during the initial steps of a surgical procedure facilitate analyzing individualized responses and thus in designing a

10 combined ablation zone that includes both an optical zone and an improved transition zone of continuous curvature, and which considers and accounts for the corrective effects of the conventional transition zone. For example, comparison of data including, but not limited to, pre-flap, post-flap, pre-ablation and post-ablation data like corneal thickness, flap thickness, corneal topography, and wave-front data provide predictive information

15 applicable to modifying an ablation pattern design.

As used herein, the term "biomechanical response" means a mechanical or physical response to a perturbation or other stimulus (e.g., cutting the cornea, ablating the cornea).

As used in this application, the term "computer component" refers to computer-

20 related entities such as hardware, firmware, software, a combination thereof, or software in execution. For example, a computer component can be, but is not limited to being, a process running on a processor, a processor, an object, an executable, a thread of execution, a program and a computer. By way of illustration, both an application running on a server and the server can be computer components. One or more computer

25 components can reside within a process and/or thread of execution and a computer component can be localized on one computer and/or distributed between two or more computers.

"Signal", as used herein, includes but is not limited to one or more electrical or optical signals, analog or digital, one or more computer instructions, a bit or bit stream,

30 or the like.

"Software", as used herein, includes but is not limited to, one or more computer readable and/or executable instructions that cause a computer or other electronic device to perform functions, actions and/or behave in a desired manner. The instructions may be embodied in various forms like routines, algorithms, modules, methods, threads,

5 and/or programs. Software may also be implemented in a variety of executable and/or loadable forms including, but not limited to, a stand-alone program, a function call (local and/or remote), a servelet, an applet, instructions stored in a memory, part of an operating system or browser, and the like. It is to be appreciated that the computer readable and/or executable instructions can be located in one computer component

10 and/or distributed between two or more communicating, co-operating, and/or parallel processing computer components and thus can be loaded and/or executed in serial, parallel, massively parallel and other manners.

In a myopic procedure, inside the ablation zone, thickness decreases as predicted by the shape subtraction model. However, outside the ablation zone, thickness

15 unexpectedly increases. In addition, regression analysis between the central and peripheral curvature changes shows a negative correlation ($p < 0.0053$), indicating that greater central flattening produces greater peripheral steepening. Elevation and pachymetry maps also show peripheral increases in both elevation and pachymetry outside the ablation zone, corresponding to the increase in curvature. Once again, the

20 shape subtraction model is found lacking, and thus ablative design patterns based on the shape subtraction model can be improved by considering individual biomechanical response to corneal structural changes and contribution of areas outside the optical zone to central vision.

Altering the corneal structure alters the shape of the entire cornea, whether using

25 an incisional, ablative or thermal mechanism. Fundamentally, if the cornea were a piece of plastic, radial keratotomy would not work. Yet, in laser refractive surgery, the structural link between the central and peripheral cornea has not been employed to design ablation patterns. Thus, this application describes systems and methods that consider peripheral stromal thickening or an increase in the corneal elevation outside the

30 optical and/or ablation zone when designing an ablation pattern. Regression analysis

-10-

between central curvature change and peripheral elevation change from thirty subjects who underwent LASIK procedures demonstrated a positive correlation (R2 = 0.56, p < 0.0001) indicating that the greater the increase in elevation outside the ablation zone, the greater the flattening curvature change centrally.

5   In one case study, regression analysis of central curvature versus peripheral stromal thickness was performed. Central curvature has a negative correlation with peripheral thickness, both inferior and superior, meaning the greater the peripheral thickness, the flatter the central curvature. Thus, the application describes example systems and methods that design ablation patterns with improved transitional zones with 10 continuous curvature based, at least in part, on peripheral stromal thickness.

          An example model is presented in Figure 6 that predicts biomechanical central corneal flattening as a direct consequence of severed corneal lamellae. Rather than modeled like a piece of plastic as with prior method, the cornea in the present invention is modeled as a series of stacked rubber bands (lamellae) with sponges between each 15 layer (interlamellaer spaces filled with ground substance or matrix). The lamellae carry a tensile load since there is a force pushing on them from underneath (intraocular pressure) and the ends are held tightly by the limbus. The amount of water that each matrix can hold is determined by how tightly the lamellae are pulled. As the lamellae are pulled more tightly, tension increases and water is squeezed out of the interleaving matrix 20 resulting in smaller, interlamellaer spacing. This is analogous to the pre-operative condition illustrated in Figure 6.

          After myopic laser refractive surgery, a series of lamellae are severed circumferentially and removed centrally as shown in Figure 6. The remaining peripheral lamellae segments relax just as tight rubber bands would relax once cut. With the 25 reduction of tension in the lamellae, the squeezing force on the matrix is reduced and the distance between lamellae expands due to negative intrastromal fluid pressure. This is analogous to the sponges taking up water if the rubber bands are cut. This allows the periphery of the cornea to thicken. Due to cross linking between the lamellae layers, the expansion force pulls on the underlying intact lamellae as indicated by the arrows 30 pointing radially outward. An outward force in the periphery pulls laterally on the center

and flattens it. Thus, the cornea will flatten centrally with procedures that circumferentially sever lamellae, including hyperopic procedures and therapeutic procedures.

The biomechanical flattening enhances a myopic procedure, works against a
5 hyperopic procedure, and causes flattening in a non-refractive PTK. This includes myopic profiles, hyperopic profiles, constant depth PTK profiles, as well as the simple cutting of a LASIK flap. Thus, the example systems and methods described herein rely on the assumption of central corneal flattening and peripheral steepening associated with severing lamellae. Figure 7 is an illustration of a customized transition zone calculated
10 according to methodology of the present invention. As shown in this illustrated example, the transition zone t_z modifies the ablation pattern A starting at the programmed optical zone S to eliminate curvature discontinuities at the edge of optical zone S. It is to be appreciated that a transition zone t_z based at least on the pre-operative data could also conceivable start at the edge or inside of the programmed optical zone S. It is to be
15 appreciated that by expanding the ablation pattern A and widening and/or deepening the transition zone t_z (i.e., the programmed optical zone correction depth), corneal crosslinks, which are preferentially distributed anteriorly and peripherally, are removed. Computational modeling indicates that applying such a transition zone pattern reduces the biomechanical response of the cornea and allows a more optimal corneal shape to be
20 achieved.

In example models employed by the systems and methods described herein, the stroma, which makes up about 90% of the total corneal thickness, most significantly influences the mechanical response of the cornea to perturbation (e.g., cutting, ablation). The stroma is approximately 78% water by weight, 15% collagen, and 7% other proteins,
25 proteoglycans, and salts. Three hundred to five hundred lamellae, flattened bundles of parallel collagen fibrils, run from limbus to limbus without interruption. In the posterior two thirds of the stroma, the lamellae are successively stacked parallel to the corneal surface so that each lamellae has an angular offset from its anterior and posterior neighbors. Anteriorly, the lamellae are more randomly oriented, often obliquely to the
30 corneal surface, are more branched, and are significantly interwoven. Accounting for the

-12-

biomechanical response of lamellar severing in the expanded transition zone facilitates improving resulting vision.

The systems and methods described herein assume that shape changes measured outside an optical zone and/or ablation zone can affect curvature changes within an
5   optical and/or ablation zone. Central curvature change in refractive surgery is not solely a product of the optical zone design pattern. When peripheral thickness and ablation zone bias are included in a regression model, over 83% of the variance and curvature response is explained by peripheral thickening. Thus, a biomechanical response considered herein assumes additional flattening over and above conventionally
10 programmed ablation profiles. This occurs in myopic (with an intent to flatten), hyperopic (with an attempt to steepen), and/or non-refractive PTK.

In LASIK surgery, cutting the flap alters the corneal structure. Following the cutting of the corneal flap, corneal measurements taken are therefore employed by example methods and systems described herein. The microkeratomic incision for the
15 flap produces changes in the cornea. The redistribution of strain caused by the keratomic incision causes the central cornea to flatten and the peripheral stroma matrix to thicken and become steeper. Such reshaping assists with a central myopic correction, where decreased corneal curvature is prescribed, and works against a hyperopic correction where increased corneal curvature is prescribed. Since cutting the LASIK flap produces
20 a biomechanical response, a method for customizing a refractive ophthalmic treatment by designing the ablation pattern with an improved optical zone plus transitional zone can include pre-operatively measuring the cornea, cutting the flap, measuring the cornea and/or the flap, calculating a customized transition zone for a designed ablation pattern, and performing an ablation based on the pattern.
25   In LASEK and PRK surgery, no flap is cut. However, based on pre-operative measurements, with reference to a biomechanical response model, an ablation pattern with an improved optical zone plus transition zone is similarly provided.

In an example method, corneal measurements are taken by methods including, but not limited to, corneal topography, optical coherence tomography, ultrasound,
30 refraction, and/or wave-front analysis. In LASIK, these measurements are taken before

-13-

and after the microkeratomic incision for the corneal flap. In LASEK and PRK, the measurements are only taken before the procedure. In LASIK, differences in corneal measurements are compared to expected and achieved post-cut results. Comparison of the measurements before and after the incision facilitate adjusting an ablative pattern

5   design to account for the measured biomechanical response due to the cutting, and the predicted biomechanical response anticipated through the ablation. Ablation pattern adjustments can thus be made in advance of the ablation in a separate procedure and/or in real time as an intraoperative adjustment after the perturbation (e.g., cut, ablation) but before the ablation.

10   Optimal surgical procedures benefit from considering the biomechanical results of the ablative procedure itself. Thus, an example LASIK surgical technique employing the systems and methods described herein includes, but is not limited to, accessing a model of predicted responses based on empirical data collected from corneas before and after cutting a flap, ablation, and healing. The technique further includes taking pre-

15 perturbation measurements (e.g., thickness profile, curvature profile, corneal size) and employing these measurements in connection with the model to facilitate computing ablation pattern designs. The method further includes taking post perturbation measurements (e.g., thickness profile, curvature profile, central flattening, peripheral thickening), and employing these measurements to compute one or more ablation

20 parameters. A sample LASEK or PRK surgical technique would only acquire pre-operative data that can be employed to query the biomechanical response model. The technique further includes comparing the differences between the pre-perturbation measurements and the post perturbation measurements to facilitate refining the computed ablation parameters and/or the model.

25   Example biomechanical response models can also consider Young's modulus measurements, and other factors including, but not limited to, age, sex, race, years of contact lens wear, thickness, curvature, and corneal size. While data concerning some factors are acquired by measuring, other data can be acquired during a patient interview (e.g., years of contact lens use). Measurements of one or more of these factors facilitate

-14-

selecting which pre-operative parameters to employ to predict a biomechanical response. Thus, ablation patterns may be designed based on pre-operative data.

Pre-operative and postoperative measurements can be input to one or more computer components by methods including, but not limited to, key stroke, direct data

5 transfer, and so on. During cornea surgery, the methods described herein may be performed on a computer system with which a surgical team member communicates. Data may be input to the computer during the surgical process. The method can then produce data, such as ablation parameters, that can be employed in subsequent steps of the surgery.

10   Those skilled in the art of computer programming, mathematical computer modeling, and/or data base manipulation and administration will readily appreciate that example systems and methods described herein may be embodied in software and/or one or more computer components. For example, Figure 8 illustrates a computer 800 that includes a processor 802, a memory 804, a disk 806, input/output ports 810, and a

15 network interface 812 operably connected by a bus 808. Executable components of systems described herein may be located on a computer like computer 800. Similarly, computer executable methods described herein may be performed on a computer like computer 800. It is to be appreciated that other computers may also be employed with the systems and methods described herein. The processor 802 can be a variety of various

20 processors including dual microprocessor and other multi-processor architectures.

The memory 804 can include volatile memory and/or non-volatile memory. The non-volatile memory can include, but is not limited to, read only memory (ROM), programmable read only memory (PROM), electrically programmable read only memory (EPROM), electrically erasable programmable read only memory (EEPROM), and the

25 like. Volatile memory can include, for example, random access memory (RAM), synchronous RAM (SRAM), dynamic RAM (DRAM), synchronous DRAM (SDRAM), double data rate SDRAM (DDR SDRAM), and direct RAM bus RAM (DRRAM). The disk 806 can include, but is not limited to, devices like a magnetic disk drive, a floppy disk drive, a tape drive, a Zip drive, a flash memory card, and/or a memory stick.

30 Furthermore, the disk 806 can include optical drives like, compact disk ROM (CD-

-15-

ROM), a CD recordable drive (CD-R drive), a CD rewriteable drive (CD-RW drive) and/or a digital versatile ROM drive (DVD ROM). The memory 804 can store processes 814 and/or data 816, for example. The disk 806 and/or memory 804 can store an operating system that controls and allocates resources of the computer 800.

5   The bus 808 can be a single internal bus interconnect architecture and/or other bus architectures. The bus 808 can be of a variety of types including, but not limited to, a memory bus or memory controller, a peripheral bus or external bus, and/or a local bus. The local bus can be of varieties including, but not limited to, an industrial standard architecture (ISA) bus, a microchannel architecture (MSA) bus, an extended ISA (EISA) 10   bus, a peripheral component interconnect (PCI) bus, a universal serial (USB) bus, and a small computer systems interface (SCSI) bus.

The computer 800 interacts with input/output devices 818 via input/output ports 810. Input/output devices 818 can include, but are not limited to, a keyboard, a microphone, a pointing and selection device, cameras, video cards, displays, and the like. 15   The input/output ports 810 can include but are not limited to, serial ports, parallel ports, and USB ports.

The computer 800 can operate in a network environment and thus is connected to a network 820 by a network interface 812. Through the network 820, the computer 800 may be logically connected to a remote computer 822. The network 820 includes, but is 20   not limited to, local area networks (LAN), wide area networks (WAN), and other networks. The network interface 812 can connect to local area network technologies including, but not limited to, fiber distributed data interface (FDDI), copper distributed data interface (CDDI), ethernet/IEEE 802.3, token ring/IEEE 802.5, and the like. Similarly, the network interface 812 can connect to wide area network technologies 25   including, but not limited to, point to point links, and circuit switching networks like integrated services digital networks (ISDN), packet switching networks, and digital subscriber lines (DSL).

In view of the exemplary systems shown and described herein, example methodologies that are implemented will be better appreciated with reference to the flow 30   diagram of Figures 9 and 10. While for purposes of simplicity of explanation, the

illustrated methodologies are shown and described as a series of blocks, it is to be
appreciated that the methodologies are not limited by the order of the blocks, as some
blocks can occur in different orders and/or concurrently with other blocks from that
shown and described. Moreover, less than all the illustrated blocks may be required to
5   implement an example methodology. Furthermore, additional and/or alternative
methodologies can employ additional, not illustrated blocks. In one example,
methodologies are implemented as computer executable instructions and/or operations,
stored on computer readable media. The computer readable media includes, but not
limited to, an application specific integrated circuit (ASIC), a compact disc (CD), a
10 digital versatile disk (DVD), a random access memory (RAM), a read only memory
(ROM), a programmable read only memory (PROM), an electronically erasable
programmable read only memory (EEPROM), a disk, a carrier wave, and a memory
stick.

In the flow diagrams, rectangular blocks denote "processing blocks" that may be
15 implemented, for example, in software. Similarly, the diamond-shaped blocks denote
"decision blocks" or "flow control blocks" that may also be implemented, for example,
in software. Alternatively, and/or additionally, the processing and decision blocks can be
implemented in functionally equivalent circuits like a digital signal processor (DSP), an
application specific integrated circuit (ASIC), and the like.

20   A flow diagram does not depict syntax for any particular programming language,
methodology, or style (e.g., procedural, object-oriented). Rather, a flow diagram
illustrates functional information one skilled in the art may employ to program software,
design circuits, and so on. It is to be appreciated that in some examples, program
elements like temporary variables, routine loops, and so on are not shown.

25   Turning now to Figure 9, a flow chart illustrates an example method 900 that
facilitates an increased functional optical zone with a customized transition zone pattern
of continuous curvature, where the corrective properties of the transition zone are
included in the ablation zone pattern design. At 910, the method 900 receives pre-
operative data concerning a cornea on which a refractive ophthalmic treatment will be
30 performed. The pre-operative data in part is used to determine a programmed optical

-17-

zone correction used in the ablation zone pattern. The pre-operative data can include, but is not limited to, topographic data, pachymetric data, elevation data, corneal thickness data, corneal curvature data, wave-front data, and intraocular pressure data, where such data are associated with the cornea before it has been perturbed. The perturbation can be

5   one of a corneal incision, a corneal ablation, a LASIK flap cut, ultrasonic measurements, and peeling the epithelial layer from the cornea, for example. It is to be appreciated that the ablation zone pattern comprises the programmed optical zone correction (pattern) and the customized transition pattern derived from the methodology of the present invention.

At 920, the method 900 subtracts the programmed optical zone correction from

10 corneal measurements provided in the pre-operative data to provide location of the programmed optical zone edge. At 930, the method 900 calculates the predicted curvature at and/or near the edge of the optical zone after application of the programmed optical zone correction. Optionally, at 935, the method 900 may receive post-perturbation data that can be used to correlate and/or recalculated the predicted curvature

15 at and/or near edge of the optical zone for further refinement.

At 940, based, at least in part, on the pre-operative data received at 910 and the predicted curvature at the edge calculated at 930, the method 900 then calculates a customized transition zone pattern which addresses curvature discontinuity by eliminating its occurrence in and/or near the programmed optical zone. In particular,

20 with the predicated curvature at and/or near the edge of the optical zone calculated at 930, the method 900 uses a curve fitting algorithm which generates a transition zone with a continuous second derivative along the profile of the cornea outwardly from the programmed optical zone correction. It is to be appreciated that any conventional curve fitting algorithm, such as spline fitting, arc-step fitting, least-squares fitting, non-linear

25 least squares fitting may be used by the present invention.

At 950, the method 950 applies the calculated transition zone to a designed ablation pattern. The ablation pattern may be designed in accordance with a biomechanical response modeled in a biomechanical response model, such as discussed in co-pending application entitled Parametric Model Based Ablative Surgical System and

30 Methods, Serial No._____, commonly assigned to The Ohio State

-18-

University, which the teachings of which is herein incorporated fully be reference. In one example, the biomechanical response model predicts the biomechanical response, at least in part, by considering the impact of severing corneal lamellae during the perturbation.

5   In an extension of method 900 (not illustrated), additional processing may be undertaken. This additional processing includes receiving post perturbation data, which can include, but is not limited to, topographic data, pachymetric data, elevation data, total corneal thickness data, corneal curvature data, wave-front data, flap thickness data, and intraocular pressure data. The perturbation can be, for example, a corneal incision,

10 a corneal ablation, a LASIK flap cut, and an epithelial layer peel. The additional processing can also include receiving post-operative diagnosis data and selectively updating the biomechanical response model based, at least in part, on the post-perturbation data and/or the post-operative diagnosis data. In this way, a predictive biomechanical response model can be updated over time to become more complete and

15 thus provide predictions that are even more accurate and thus better designs. The post-operative diagnosis data can include, but is not limited to, patient satisfaction data, patient vision data, patient halo effect data, topographic data, pachymetric data, elevation data, total corneal thickness data, corneal curvature data, wave-front data, and intraocular pressure data.

20   Turning now to Figure 10, a system 1000 for calculating a customized transition zone, which addresses curvature discontinuities in a programmed optical zone correction, is illustrated. The system 1000 includes a data receiver 1010 that receives corneal data 1020. The corneal data 1020 can include, but is not limited to, topographic data, pachymetric data, elevation data, total corneal thickness data, corneal curvature data,

25 wave-front data, and intraocular pressure data measured before and/or after a cornea is processed by at least one of a cut, an ablation, and an epithelial peel. In LASEK and PRK, the corneal data will not include post-perturbation data, with the design being based on pre-operative measurements with reference to a biomechanical response model, such for example, as discussed in co-pending application entitled Parametric Model

30 Based Ablative Surgical System and Methods, Serial No._____,

-19-

commonly assigned to The Ohio State University, which the teachings of which is herein incorporated fully be reference.

The system 1000 may also optionally include a predictive corneal curvature model 1030. The predictive corneal curvature model 1030 facilitates selecting a
5 transition zone curvature based on the corneal data 1020. The system 1000 includes a transition zone designer 1040 that computes the transition zone curvature pattern 1050. The designer 1040 produces a customized transition zone pattern of continuous curvature which eliminates curvature discontinuities at or near the edge of the post-operative optical zone and whose effects on minimizing the biomechanical response can then be
10 applied and accounted for in an ablation zone design.

Turning now to Figure 11, a simulated tangential map and a simulated refractive power map associated with a theoretical pre-operative cornea are illustrated. On the tangential map warmer colors (e.g., yellow, red) represent more curved areas. On the refractive map, the warmer colors represent areas of greater power. Conversely, cooler
15 colors (blue, purple) represent areas of lesser curvature on the tangential map, and lower power on the refractive map. Thus, in Figure 11, the tangential map illustrates that the cornea is steeper in the middle and flatter in the periphery, thereby graphically illustrating a typical myopic cornea.

Figure 12 illustrates a simulated tangential map and a simulated refractive power
20 map for a theoretical post-operative cornea, where the data set used represents a cornea ablated using a conventional transition zone and ablation algorithm. The tangential map illustrates a central flattening as compared to the pre-operative cornea of Figure 11, and the characteristic red ring that indicates a very steep area caused by a sub-optimal transition zone design and peripheral biomechanical response. The refractive power map
25 has a characteristically small central blue area that can be improved using the systems and methods described herein.

Figure 13 illustrates a tangential map and a refractive power map for a theoretical post-operative cornea, where the data set used represents a cornea ablated using the customized transition zone described herein in an ablation pattern. In both Figures 12
30 and 13, the resulting theoretical post-operative corneas, which had substantially the same

-20-

optical zone size and central flattening, applied programmed corrections based on the
Munnerlyn formulae. However, unlike that of the post-operative cornea of Figure 12,
the tangential map of Figure 13 illustrates that the red ring indicating an area of curvature
discontinuities has been moved further away from the center of the cornea. This
5 facilitates mitigating problems associated with spherical aberration. In addition, by
applying the customized transition zone, a larger area of improved curvature can be
achieved. For example, in the refractive power map of Figure 13, the central blue area is
much larger than that of Figure 12, indicating a larger, more useful area of corrected
vision, with fewer effects of spherical aberration.

10   What has been described above includes several examples. It is, of course, not
possible to describe every conceivable combination of components or methodologies for
purposes of describing the methods, systems, computer readable media and so on
employed in improving the computation of ablation parameters. However, one of
ordinary skill in the art may recognize that further combinations and permutations are
15 possible. Accordingly, this application is intended to embrace alterations, modifications,
and variations that fall within the scope of the appended claims. Furthermore, to the
extent that the term "includes" is employed in the detailed description or the claims, it is
intended to be inclusive in a manner similar to the term "comprising" as that term is
interpreted when employed as a transitional word in a claim.
